Arithmetic Operations on Matrices

- They are frequent in scientific computing areas, for example in signal and image processing, document retrieval, and feature selection.
- Those operations usually become a performance bottleneck due to their high computational complexity.
- The parallel processing of matrix operations in distributed memory architectures arises as an important issue to study.
- The operations with **dense** matrices have been the subject of intensive research.

Arithmetic Operations on Matrices Motivation

- In text analysis, as in collaborative filtering and document clustering, matrices are sparse.
- The performance of sparse matrix operations tends to be lower than the dense matrix equivalent.
- Algorithms that are efficient for dense representations are not suitable for sparse representations.
- This paper aims at studying the performance of several strategies for distributing sparse-matrix arithmetic operations on computer clusters.

Basic Definitions Parallel-Factor

 $\mathsf{Parallel}\operatorname{-Factor} = \lfloor \#\mathsf{physical}\operatorname{-cores} \times (1 + \alpha + \gamma) \rfloor$

- Focus on the intrinsic characteristics of the operations and their associated matrices.
- Used to determine the number of rows assigned to each parallel task to be created and executed.
- Inversely related to the number of rows per tasks.
- As it might be zero, an additional constraint is introduced.
- Computed for three types of operations: Addition-Subtraction, Matrix Multiplication and Laplacian.

Basic Definitions

$$\gamma = \begin{cases} 1 - \log\left(\frac{\# rows}{\# columns}\right) & \# rows \le \# columns\\ 1 - \log\left(\frac{\# columns}{\# rows}\right) & \# rows > \# columns \end{cases}$$

- Defined as the ratio of the number of rows and columns.
- Shared by all the strategies.

ISISTAN Research Institute, CONICET

Strategies Row-Sparseness

$$lpha = 1 - \overline{\left(rac{\mathsf{non-zero}_i}{\#\mathit{columns}}
ight)}$$

- The general sparseness of a matrix might not accurately capture the sparseness of each particular row.
- Considers the mean row sparseness of the matrix.
- Aims at establishing an inverse relation between the PF and the row sparseness.

A. Tommasel, C. Mateos, D. Godoy and A. Zunino

ISISTAN Research Institute, CONICET

Strategies Row-Sparseness Standard-Deviation

$$\alpha = 1 - \left(\overline{\left(\frac{\mathsf{non-zero}_i}{\#columns}\right)} - \sigma\left(\frac{\mathsf{non-zero}_i}{\#columns}\right)\right)$$

- Standard deviation measures de the dispersion of data from the mean.
- Aims at adding information regarding the existence of outliers.
- Considers the lowest sparseness value in the normal distribution.

A. Tommasel, C. Mateos, D. Godoy and A. Zunino

ISISTAN Research Institute, CONICET

Strategies Mode

$$lpha = 1 - \mathsf{most-frequent}\left\{rac{\mathsf{non-zero}_i}{\#\mathit{columns}}
ight\}$$

- Favours the most common sparseness value.
- May not accurately represent the data. There may be more than one value, or not value at all.
- Could cause an unbalanced distribution of rows per tasks.

A. Tommasel, C. Mateos, D. Godoy and A. Zunino

ISISTAN Research Institute, CONICET

Strategies _{Static}

 $\mathsf{Parallel}\operatorname{Factor} = \lfloor \#\mathsf{physical}\operatorname{-cores} \times \mathsf{granularity}\operatorname{-factor} \rfloor$

- Independent of the characteristics of the matrices involved.
- Allows to directly control the extend to which the operation is divided into tasks.
- Allows the creation of an arbitrary number of tasks. [ESTA O LA ANTERIOR]
- Strategy used for the Laplacian operation.

Feature Selection

- Strategies were evaluated for a feature selection approach.
- Considered not only features and posts, but also social context of post and user relationships.
- Social interactions lead to different types of relations.
- Based on high-dimensional matrices and arithmetic operations between them.

$$B = XX^T + \beta F L_A F^T$$

$$E = Y^T X^T = (XY)^T$$

Implementation

- Java was the programming language chosen for implementing the approach.
- Matrices were implemented as sparse memory structures in order to decrease the storage and network transfer requirements.
- The distribution and execution of tasks on the computer cluster was performed by using the Java Parallel Processing Framework (JPPF) middleware.
- The baseline for comparing and evaluating the enhancements introduced was the execution of all the operations in a serial and a multi-thread manner.

ISISTAN Research Institute, CONICET

Summary

- This work aimed at studying the performance of several strategies for distributing sparse matrix arithmetic operations on computer clusters.
- The strategies focused on the intrinsic characteristics of the operations and their associated matrices.
- The performance of the proposed strategies was evaluated considering a high-dimensional feature selection approach.
- Two different implementation for sparse matrices were tested.

A. Tommasel, C. Mateos, D. Godoy and A. Zunino

ISISTAN Research Institute, CONICET

Conclusions

- The performance of the *Trove* representation of matrices was superior to the *HashMap*.
- The computer cluster executions outperformed the Serial and Multi-Thread executions when big-scale matrices were involved.
- The *Multi-Thread* executions tended to perform better than the computer cluster executions when small matrices were involved.
- Results stated the importance of considering the intrinsic characteristics of the matrices involved.
- The time spent computing the *PF* did not affect the overall performance of the strategies.

Conclusions
